Investobot

Software to manage risk in leveraged index tracking ETFs

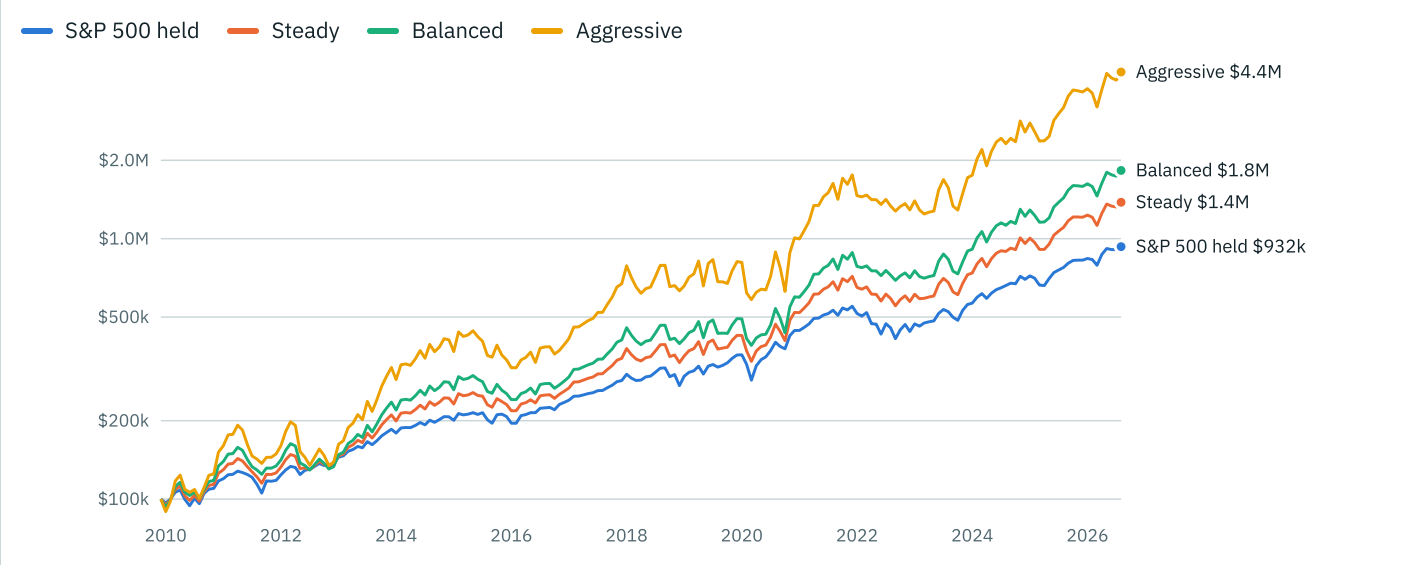

It's difficult to beat the S&P 500. So if you can't beat them, join them.

Leverage makes sense when the market is up and can be disastrous in a downturn. Investobot holds the S&P 500 through leveraged index funds, adds exposure while the market is above trend, and cuts it when trend or volatility breaks.

More of the market when it's working. Less when it isn't.

Deterministic rules, easy to follow. Your account, on your machine.

HYPOTHETICAL GROWTH OF $100,000, 2010 TO 2026, LOG SCALE

Simulated, not traded. 2010 to 2026 was a strong period for leverage and misses 1929, 1973, 2000 and 2008; the figures below cover every market since 1928. The rule was chosen on this same history, which flatters the result. Fund costs included, taxes excluded.

Tested on market data back to 1928, every setting finished ahead of the S&P, and the Balanced setting did it with a smaller worst drop. You run it yourself, and you pay once for setup.

14.4% vs 9.6%

Balanced vs S&P, simulated return per year, 1928 to 2026

–71% vs –84%

Balanced vs S&P, worst simulated drop on the same history

$0 of assets

We never hold your money. No percentage fee and no performance fee.

THREE SETTINGS, 20-YEAR HOLD, $100,000 START

Setting	Worst 5% of paths, per year	Typical, per year	Best 5% of paths, per year	Ending value, worst 5%	Ending value, typical	Chance of a 50% drop	Chance of a 75% drop	Worst drop, 1928 on
Steady Half S&P held, half 2x rule	3.3%	12.2%	21.7%	$193k	$1.0M	34%	3%	−76%
Balanced 2x rule	3.9%	13.7%	24.5%	$215k	$1.3M	39%	2%	−71%
Aggressive 3x rule	3.1%	17.5%	34.1%	$186k	$2.5M	85%	16%	−84%
S&P held For comparison	1.8%	9.9%	17.0%	$142k	$663k	45%	7%	−84%

Hypothetical, before tax, with estimated fund costs. 1,000 simulated paths built by resampling daily US market returns since 1926.

THE RULE

- **Step out** when the S&P closes below its 150-day average, or 20-day volatility rises above 25%.
- **While out,** hold half S&P and half T-bills.
- **Step back in** after 3 closes in a row above the 100-day exponential average.

Trades happen at the close after the signal, about 5 times a year. You can read every line of the code.

HOW IT RUNS AND WHAT YOU PAY

- Runs on a VPS you rent, connected to your brokerage account with your own keys.
- You pick the setting and can switch it off at any time.
- We keep no access after setup.
- **[Setup fee]**, once. You also pay your VPS and broker, and the funds charge about 0.9% a year.

WHAT CAN GO WRONG

- Day-to-day swings run larger than the S&P on every setting. Aggressive will probably lose more than half at some point.
- Crashes can move faster than the rule. One bad day can cost a third or more at 3x.
- The edge depends on market trends lasting. In simulated markets with the trends removed, switching rules lost to holding the S&P.
- With T-bills at 6%, typical Aggressive falls to 13.5% and its worst 5% to 0.9%.
- The future can be worse than anything in the record.

TAXES

Switching realizes gains, so the account type matters. Typical Aggressive return after federal tax:

- IRA or Roth: 18.2% a year
- Taxable, S&P held plus index futures: 16.7%
- Taxable, leveraged funds: 15.3%

Assumes 24% ordinary and 15% long-term rates, no state tax. Talk to a tax professional.

This page describes software. It is not investment, tax or legal advice or a recommendation to buy any security. Leveraged funds reset daily and can lose most of their value. All figures are hypothetical, come from simulations with the benefit of hindsight, and do not reflect actual trading. No account has traded these rules and no one has earned these returns. Simulations cannot capture every cost, including slippage, tax on dividends and fund changes. Past market behavior does not predict future results. You can lose most of your investment. "S&P 500" is a trademark of its owner, and this product has no connection to it.
